This user manual provides information on running and using the UNICORE Gateway. Please note also the following places for getting more information:

UNICORE Website: https://www.unicore.eu Support list: unicore-support@lists.sf.net Developer's list: unicore-devel@lists.sf.net

GitHub page: https://github.com/UNICORE-EU/gateway

### 1 Introduction

The Gateway is the entry point into a UNICORE site, routing HTTPS traffic to servers like UNICORE/X. It forwards client traffic to the intended destination, optionally authenticating the client. The Gateway receives the reply and sends it back to the client. In this way, only a single open port in a site's firewall has to be configured.

#### **LIMITATIONS**

The Gateway is not a complete HTTP reverse proxy implementation. For example, it is not possible to run a full, complex web application "behind" the Gateway, especially not if protocols like WebSocket are used.

In effect, traffic to a *virtual URL*, e.g. *https://mygateway:8088/Alpha* is forwarded to the real URL, e.g. *https://host1:7777*.

The mappings of virtual URL to real URL for the available sites are listed in a configuration file connections.properties. Additionally, the Gateway supports dynamic registration of sites.

The second functionality of the Gateway is (optional) authentication of incoming requests. Connections to the Gateway are made using SSL, so the Gateway can be configured to check whether the caller presents a certificate issued by a trusted authority. Information about the client is forwarded to services behind the Gateway in UNICORE proprietary format (as a SOAP or HTTP header).

The Gateway will forward the IP address of the client to the back-end server.

Last not least, the Gateway can be configured as a HTTP load balancer.

#### **IMPORTANT NOTE ON PATHS**

The UNICORE Gateway is distributed either as a platform independent and portable bundle (as a part of the UNICORE core server package) or as an installable, platform dependent package format such as RPM.

Depending on the installation method, the paths to various Gateway files are different. If installing using a distribution-specific package the following paths are used:

```
CONF=/etc/unicore/gateway
BIN=/usr/sbin
LOG=/var/log/unicore/gateway
```

If installing using the portable bundle all Gateway files are installed under a single directory. Path prefixes then are as follows, where INST is a directory where the Gateway was installed:

```
CONF=INST/conf
BIN=INST/bin
LOG=INST/logs
```

The above variables (CONF, BIN and LOG) are used throughout the rest of this manual.

## 2 Installation

The UNICORE Gateway is distributed in the following formats:

- As a part of platform independent installation bundle called UNICORE Server bundle.
   The UNICORE Server bundle is provided as a tar package and includes a command line installer.
- As a binary, platform-specific package available currently for RedHat (Centos) and Debian platforms. Those packages are not tested on all possible platforms, but should work without any problems with other versions of similar distributions, e.g. SL, Centos, or Fedora.

To run, the Gateway requires Java (JRE headless is sufficient) in version 8 or later. We recommend using OpenJDK.

## 2.1 Installation from the Server bundle

Download the server bundle from the UNICORE project website.

Please review the README file available after extracting the bundle. You don't have to change any defaults as the Gateway is installed by default.

You should create and use a system user (e.g. *unicore*) to install and run the gateway. For security reasons, do not run the Gateway as the *root* user.

## 2.2 Installation from a Linux package (rpm or deb)

Use your distribution's package manager to install.

## 3 Upgrading

The general update procedure is presented below, with possible variations:

- 1. Stop the old Gateway.
- 2. Update the server package. This step mostly applies for RPM/DEB managed installations. For Quickstart installation it is enough to replace the \*.jar files with the new ones.
- 3. Start the newly installed Gateway.
- 4. Verify log file and fix any problems reported.

## 4 Configuration

The Gateway is configured using a set of configuration files, which reside in the CONF subdirectory.

### 4.1 Java and environment settings: startup.properties

This file contains settings related to the Java VM, such as the Java command to use, memory settings, library paths etc.

### 4.2 Configuring sites: connections.properties

This is a simple list connecting the names of sites and their physical addresses. An example is:

```
DEMO-SITE = https://localhost:7777
REGISTRY = https://localhost:7778
```

If this file is modified, the Gateway will re-read it at runtime, so there is no need to restart the Gateway in order to add or remove sites.

Optionally administrator can enable a possibility for dynamic site registration at runtime, see Section 4.3.3 for details. Then this file should contain only the static entries (or none if all sites register dynamically).

Further options for back-end sites configuration are presented in Section 6.

## 4.3 Main server settings: gateway.properties

Use the gateway.hostname property to configure the network interface and port the Gateway will listen on. You can also select between https and http protocol, though in almost all cases https will be used.

### Example:

```
gateway.hostname = https://192.168.100.123:8080
```

### Note

If you set the host to 0.0.0.0, the Gateway will listen on all network interfaces of the host machine, else it will listen only on the specified one.

If the scheme of the hostname URL is set to https, the Gateway uses the configuration data from security.properties to configure the HTTPS settings.

### 4.3.1 Credential and truststore settings

The Gateway credential and truststore is configured using the following properties

Property name	Type	Default	Description
		value /	
		mandatory	
gateway.credentia	1 filesystem path	mandatory to be set	Credential location. In case of <i>jks</i> , <i>pkcs12</i> and <i>pem</i> store it is the only location required. In case when credential is provided in two files, it is the certificate file path.
gateway.credentia	l [jks] pkest12, der, pem]	-	Format of the credential. It is guessed when not given. Note that <i>pem</i> might be either a PEM keystore with certificates and keys (in PEM format) or a pair of PEM files (one with certificate and second with private key).
gateway.credentia	l <b>stpiag</b> sword	-	Password required to load the credential.

Property name	Туре	Default	Description
		value /	
gateway.credentia	l etking Da+ h	mandatory	Location of the private key
gateway.credentia	T 2001 H Z L A C II	-	if stored separately from
			the main credential
			(applicable for <i>pem</i> and <i>der</i>
	_		types only),
gateway.credentia	l <b>strieg</b> Password	<del>-</del>	Private key password,
			which might be needed
			only for jks or pkcs12, if
			key is encrypted with
			different password then the
			main credential password.
gateway.credentia	l <b>stkieg</b> Alias	-	Keystore alias of the key
			entry to be used. Can be
			ignored if the keystore
			contains only one key entry.
			Only applicable for <i>jks</i> and
			pkcs12.

Property name	Type	Default	Description	
		value /		
		mandatory

#### 4.3.2 Scalability settings

To fine-tune the operational parameters of the embedded Jetty server, you can set advanced HTTP server parameters. See [?informaltable] for details. Among others you can use the non-blocking IO connector offered by Jetty, which will scale up to higher numbers of concurrent connections than the default connector.

The Gateway acts as a https client for the VSites behind it. The number of concurrent calls is limited, and controlled by two parameters:

```
# maximum total number of concurrent calls to Vsites
gateway.client.maxTotal=100
# total number of concurrent calls per site
gateway.client.maxPerService=20
```

You can also control the limit on the maximum SOAP header size which is allowed by the Gateway. **Typically you don't have to touch this parameter**. However if your clients do produce very big SOAP headers and the Gateway blocks them, you can increase the limit. Note that such a giant SOAP header usually means that the client is not behaving in a sane way, e.g. is trying to perform a DoS attack.

```
# maximum size of an accepted SOAP header, in bytes
gateway.soapMaxHeader=102400
```

Note that Gateway may consume this amount of memory (plus some extra amount for other data) for each opened connection. Therefore, this value multiplied by the number of maximum allowed connections, should be significantly lower, then the total memory available for the Gateway.

## 4.3.3 Dynamic registration of Vsites

Dynamic registration is controlled by three properties in CONF/gateway.properties file:

```
gateway.registration.enable=true
gateway.registration.secret=<your secret>
```

If set to true, the Gateway will accept dynamic registrations which are made by sending a HTTP POST request to the URL /VSITE\_REGISTRATION\_REQUEST This request must contain a parameter "secret" which matches the value configured in the gateway.properties file

Filters can be set to forbid access of certain hosts, or to require certain strings in the Vsite addresses. For example:

```
gateway.registration.deny=foo.org example.org
```

will deny registration if the remote hostname contains foo.org or example.org. Conversely,

```
gateway.registration.allow=mydomain.org
```

will only accept registrations if the remote address contains *mydomain.org*. These two (deny and allow) can be combined.

### 4.3.4 Web interface ("monkey page")

For testing and simple monitoring purposes, the Gateway displays a website showing detailed site information (the details view can be disabled). Once the Gateway is running, open up a browser and navigate to <a href="https://cgateway\_host>:8080">https://cgateway\_host>:8080</a> (or whichever URL the gateway is running on). If the Gateway is configured to do SSL authentication, you will need to import a suitable client certificate into your web browser.

A HTML form for testing the dynamic registration is available as well, by clicking the link in the footer of the main Gateway page.

To disable the Vsite details page, set

gateway.disableWebpage=true

## 4.3.5 Main options reference

Property name	Туре	Default value / mandatory	Description
gateway.hostname	string	mandatory	external gateway bind
gateway.registrat		to be set	Space separated list of allowed hosts for dynamic registration.
gateway.registrat	i.stningleny	-	Space separated list of denied hosts for dynamic registration.
gateway.registrat	i [true⊋ fækse] e	false	Whether dynamic registration of sites is enabled.
gateway.registrat	i <b>stning</b> ecret	-	Required secret for dynamic registration.
	Passing Co	nsignor info	
gateway.consignor	TinkegeT≥meDTole	rânce	The validity time of the authenticated client information passed to backend sites will start that many seconds before the real authentication. It is used to mask time synchronization problems between machines.

Property name	Туре	Default	Description
		value / mandatory	
gateway.consignor	T <b>inkegeV≥</b> ±ildity		What is the validity time of the authenticated client information passed to backend sites. Increase it if there machines clocks are not synhronized.
gateway.signConsi		false	Controls whether information about the authenticated client (the consignor) passed to backend sites should be signed, or not. Signing is slower, but is required when sites may be reached directly, bypassing the Gateway.
		Site client	
gateway.client.ch	u [tkædfalse]	true	Controls whether chunked passing of HTTP requests to backend sites is supported.
gateway.client.co	n <b>integei onfibe</b> re o	u <b>£</b> 0000	Connection timeout, used when connecting to backend sites.
gateway.client.ex	p <b>(trute¢ false)</b> nue	true	Controls whether the HTTP expec-continue mechanism is enaled on connections to backend sites.
gateway.client.gz		true	Controls whether support for compression is announced to backend sites.
gateway.client.ke		true	Whether to keep alive the connections to backend sites.
gateway.client.ma		20	Maximum allowed number of connections per backend site.
gateway.client.ma	x integeit number	100	Maximum total number of connections to backend sites allowed.
gateway.client.so	c inntgei member	30000	Connection timeout, used when connecting to backend sites.

Property name	Туре	Default value /	Description
		mandatory	
gateway.httpServe	r <b>innegeC⊘</b> nnOecti		Maximum number of incoming connections to this server. If set to a value larger than 0, incoming connections will be limited to that number. Default is 0 = unlimited.
gateway.httpServe			Time (in ms.) before an idle connection will time out. It should be large enough not to expire connections with slow clients, values below 30s are getting quite risky.
gateway.httpServe		255	Maximum number of threads to have in the thread pool for processing HTTP connections. Note that this number will be increased with few additional threads to handle connectors.
gateway.httpServe	r <b>intdgeT≽</b> ≢ <b>d</b> ads	1	Minimum number of threads to have in the thread pool for processing HTTP connections. Note that this number will be increased with few additional threads to handle connectors.
gateway.httpServe	r[t <b>rue</b> gfalse∳Cli∈	nt Awehn	Controls whether the SSL socket requires client-side authentication.
gateway.httpServe		true	DEPRECATED, no effect
gateway.httpServe			Controls whether the SSL socket accepts (but does not require) client-side authentication.
gateway.httpServe	r <b>string</b> ameAllow	tekaittp://lo	c Land weigin that is allowed to embed web interface inside a (i)frame.  Meaningful only if the xFrameOptions is set to allowFrom. The value should be in the form: http[s]://host[:port]

Property name	Type	Default	Description
		value /	
		mandatory	
gateway.httpServe	r <b>[deny</b> ,ameOptic	nosteny	Defines whether a
	sameOrigin,		clickjacking prevention
	allowFrom,		should be turned on, by
	allow]		insertionof the
			X-Frame-Options HTTP
			header. The <i>allow</i> value
			disables the feature. See the
			RFC 7034 for details. Note
			that for the <i>allowFrom</i> you
			should define also the
			xFrameAllowed option and
			it is not fully supported by
			all the browsers.

## 4.4 Require end-user certificates

Using client certificates for end-user authentication are not required or recommended. If you still want to require end-users to have a certificate, end-user certificates, the Gateway can be configured accordingly. Set the following in gateway.properties

gateway.httpServer.requireClientAuthn=true

# 4.4.1 Logging

UNICORE uses Log4j (version 2) as its logging framework, and comes with an example configuration file (CONF/logging.properties)

Please refer to the Log4j documentation for more information https://logging.apache.org/log4j/-2.x/manual/configuration.html

The most important, root log categories used by the Gateway's logging are:

unicore.gateway	General Gateway logging
unicore.security	Certificate details and other security
org.apache.http	Outgoing HTTP to the backend services

# 5 Using Apache httpd as a frontend

You may wish to use the Apache webserver (httpd) as a frontent for the Gateway (e.g. for security or fault-tolerance reasons).

#### Requirements

- · Apache httpd
- mod\_proxy for Apache httpd

#### **External references**

• https://wiki.eclipse.org/Jetty/Howto/Configure\_mod\_proxy

# 6 Using the Gateway for failover and/or loadbalancing of UNI-CORE sites

The Gateway can be used as a simple failover solution and/or loadbalancer to achieve high availability and/or higher scalability of UNICORE/X sites without additional tools.

A site definition (in CONF/connections.properties) can be extended, so that multiple physical servers are used for a single virtual site.

An example for such a so-called multi-site declaration in the connections.properties file looks as follows:

```
#declare a multisite with two physical servers

MYSITE=multisite:vsites=https://localhost:7788 https://localhost ↔
:7789
```

This will tell the Gateway that the virtual site "MYSITE" is indeed a multi-site with the two given physical sites.

## 6.1 Configuration

Configuration options for the multi-site can be passed in two ways. On the one hand they can go into the connections.properties file, by putting them in the multi-site definition, separated by ";" characters:

```
#declare a multisite with parameters

MYSITE=multisite:param1=value1;param2=value2;param3=value3;...
```

#### The following general parameters exist

vsites	List of physical sites
strategy	Class name of the site selection strategy to
	use (see below)
config	Name of a file containing additional
	parameters

Using the "config" option, all the parameters can be placed in a separate file for enhanced readability. For example you could define in connections.properties:

```
#declare a multisite with parameters read from a separate file
MYSITE=multisite:config=conf/mysite-cluster.properties
```

and give the details in the file "conf/mysite-cluster.properties":

```
#example multisite configuration
vsites=https://localhost:7788 https://localhost:7789

#check site health at most every 5 seconds
strategy.healthcheck.interval=5000
```

## 6.2 Available strategies

A selection strategy is used to decide where a client request will be routed. By default, the strategy is "Primary with fallback", i.e. the request will go to the first site if it is available, otherwise it will go to the second site.

### Primary with fallback

This strategy is suitable for a high-availability scenario, where a secondary site takes over the work in case the primary one goes down for maintenance or due to a problem. This is the default strategy, so nothing needs to be configured to enable it. If you want to explicitly enable it anyway, set

```
strategy=primaryWithFallback
```

The strategy will select from the first two defined physical sites. The first, primary one will be used if it is available, else the second one. Health check is done on each request, but not more frequently as specified by the "strategy.healthcheck.interval" parameter. By default, this parameter is set to 5000 milliseconds.

Changes to the site health will be logged at "INFO" level, so you can see when the sites go up or down.

## Round robin

This strategy is suitable for a load-balancing scenario, where a random site will be chosen from the available ones. To enable it, set

```
strategy=roundRobin
```

Changes to the site health will be logged at "INFO" level, so you can see when the sites go up or down.

It is very important to be aware that this strategy requires that all backend sites used in the pool, share a common persistence. It is because Gateway does not track clients, so particular client

requests may land at different sites. This is typically solved by using a non-default, shared database for sites, such as MySQL.

#### Note

Currently loadbalancing of target sites is an experimental feature and is not yet fully functional. It will be improved in future UNICORE versions.

#### **Custom strategy**

You can implement and use your own failover strategy, in this case, use the name of the Java class as strategy name:

strategy=your\_class\_name

# 7 Gateway failover and migration

The Section 6 covered usage of the Gateway to provide failover of backend services. However it may be needed to guarantee high-availabilty for the Gateway itself or to move it to other machine in case of the original one's failure.

## 7.1 Gateway's migration

The Gateway does not store any state information, therefore its migration is easy. It is enough to install the Gateway at the target machine (or even to simply copy it in the case of installation from the core server bundle) and to make sure that the original Gateway's configuration is preserved.

If the new machine uses a different address, it needs to be reflected in the server's configuration file (the listen address). Also, the configuration of sites behind the Gateway must be updated accordingly.

## 7.2 Failover and loadbalancing of the Gateway

Gateway itself doesn't provide any features related to its own redundancy. However as it is stateless, the standard redundancy solutions can be used.

The simpliest solution is to use Round Robin DNS, where DNS server routes the Gateway's DNS address to a pool of real IP addresses. While easy to set up this solution has a significant drawback: DNS server doesn't care about machines being down.

The much better choice is to use the Linux-HA software suite, often known under the name of its principal component, the *heartbeat*. For details see <a href="http://www.linux-ha.org">http://www.linux-ha.org</a>

Additionally a more advanced HTTP-aware software can be used, such as HA-Proxy (http://haproxy.1wt.eu). Currently Gateway and UNICORE don't maintain HTTP sessions so usage of the HTTP-aware load-balancer is not strictly required, but such solutions generally provide more general purpose features.

# 8 Building the Gateway from source

To checkout the latest version of the Gateway source code, do

```
git clone https://github.com/UNICORE-EU/gateway.git
cd gateway
```

You will need to install Maven from http://maven.apache.org Compile using

```
mvn install
```

which compiles the code and runs the tests.

The file "README-building.txt" contains instructions for building distributable packages.
